Where We've Been, Where We're Going

In the previous Lecture

- Univariate and Multivariate Change of Variables
- Markov's Inequality
- Chebyshev's Inequality
- Weak Law of Large Numbers
- Exercises & Questions

Today

- Weak Law of Large Numbers: Interpretation and discussion
- Convergence in probability
- Convergence in distribution
- Central limit theorem

Why are we studying limit theorems?

Questions we are addressing

- What happens when we consider a long sequence of random variables ?
- What can we reasonably infer from data?
- Laws of large numbers: averages of random variables converge on expected value?
- Central Limit Theorems: sum of random variables have normal distribution?

Sequence of Random Variables

Sequence of Independent and Identically, Distributed Random variables.

- Sequence: $X_1, X_2, \dots, X_n, \dots$
- Think of a sequence as sampled **data**:
 - Suppose we are drawing a sample of N observations
 - Each observation will be a **random variable**, say X_i
 - With realization x_i

Mean/Variance of Sample Mean

Sample Mean

Let X_1, X_2, \dots, X_n be a random sample from a distribution with mean μ and variance σ^2 . Let \bar{X}_n be the sample mean. Then $E[\bar{X}_n] = \mu$ and $\text{var}(\bar{X}_n) = \frac{\sigma^2}{n}$

Proof.

$$E[\bar{X}_n] = \frac{1}{n} \sum_{i=1}^n E[X_i] = \frac{1}{n} n\mu = \mu$$

$$\text{var}(\bar{X}_n) = \frac{1}{n^2} \text{var}\left(\sum_{i=1}^n X_i\right) = \frac{1}{n^2} \sum_{i=1}^n \text{var}(X_i) = \frac{1}{n^2} n\sigma^2 = \frac{\sigma^2}{n}$$

Weak Law of Large Numbers

Proposition

Suppose X_1, X_2, \dots, X_n is a random sample from a distribution with mean μ and $\text{Var}(X_i) = \sigma^2$. Then, for all $\epsilon > 0$,

$$P \left\{ \left| \frac{X_1 + X_2 + \dots + X_n}{n} - \mu \right| \geq \epsilon \right\} \rightarrow 0 \text{ as } n \rightarrow \infty$$

Weak Law of Large Numbers

Interpretation

It is a common belief that if we toss a coin textitmany times, the propostion of heads will be close to $\frac{1}{2}$.

The law of large numbers is a mathematical interpretation of this believe!

Example

- Successive tosses of a coin can be modelled as independent random trials X_i
- Each X_i takes on 0 (if the i – *th* result is tail) or 1 (if the i – *th* result is head)
- The proportion of heads in n trials is $\bar{X} = \frac{1}{n} \sum_{i=1}^n X_i$

The law of large numbers says that \bar{X} approaches μ as the number of trials grows.

Sequences and Convergence: Recalls

Sequence of real numbers:

$$\{a_i\}_{i=1}^{\infty} = \{a_1, a_2, a_3, \dots, a_n, \dots, \}$$

Definition

We say that the sequence $\{a_i\}_{i=1}^{\infty}$ converges to real number A if for each $\epsilon > 0$ there is a positive integer N such that for $n \geq N$, $|a_n - A| < \epsilon$

Sequences and Convergence

Sequence of functions:

$$\{f_i\}_{i=1}^{\infty} = \{f_1, f_2, f_3, \dots, f_n, \dots, \}$$

Definition

Suppose $f_i : X \rightarrow \mathfrak{R}$ for all i . Then $\{f_i\}_{i=1}^{\infty}$ converges **pointwise** to f if, for all $x \in X$ and $\epsilon > 0$, there is an N such that for all $n \geq N$,

$$|f_n(x) - f(x)| < \epsilon$$

This is as strong of a statement!

Convergence: Some Definitions

Let $\hat{\theta}_i$ be an estimator for θ based on i observations.

Convergence: Some Definitions

Let $\hat{\theta}_i$ be an estimator for θ based on i observations.
Increasing sample size we get a **Sequence** of estimators:

$$\{\hat{\theta}_i\}_{i=1}^n = \{\hat{\theta}_1, \hat{\theta}_2, \hat{\theta}_3, \dots, \hat{\theta}_n\}$$

Question: What can we say about $\{\hat{\theta}_i\}_{i=1}^n$ as $n \rightarrow \infty$?

- What is the probability $\hat{\theta}_n$ differs from θ ?

Convergence: Some Definitions

Let $\hat{\theta}_i$ be an estimator for θ based on i observations.
Increasing sample size we get a **Sequence** of estimators:

$$\{\hat{\theta}_i\}_{i=1}^n = \{\hat{\theta}_1, \hat{\theta}_2, \hat{\theta}_3, \dots, \hat{\theta}_n\}$$

Question: What can we say about $\{\hat{\theta}_i\}_{i=1}^n$ as $n \rightarrow \infty$?

- What is the probability $\hat{\theta}_n$ differs from θ ?
- What is the probability $\{\hat{\theta}_i\}_{i=1}^n$ converges to θ ?

Convergence: Some Definitions

Let $\hat{\theta}_i$ be an estimator for θ based on i observations.
Increasing sample size we get a **Sequence** of estimators:

$$\{\hat{\theta}_i\}_{i=1}^n = \{\hat{\theta}_1, \hat{\theta}_2, \hat{\theta}_3, \dots, \hat{\theta}_n\}$$

Question: What can we say about $\{\hat{\theta}_i\}_{i=1}^n$ as $n \rightarrow \infty$?

- What is the probability $\hat{\theta}_n$ differs from θ ?
- What is the probability $\{\hat{\theta}_i\}_{i=1}^n$ converges to θ ?

Convergence in Probability

Definition

We will say the sequence $\hat{\theta}_n$ converges in probability to θ (perhaps a non-degenerate RV) if,

$$\lim_{n \rightarrow \infty} \text{Prob}(|\hat{\theta}_n - \theta| > \epsilon) = 0$$

For any $\epsilon > 0$

Convergence in Probability

Definition

We will say the sequence $\hat{\theta}_n$ converges in probability to θ (perhaps a non-degenerate RV) if,

$$\lim_{n \rightarrow \infty} \text{Prob}(|\hat{\theta}_n - \theta| > \epsilon) = 0$$

For any $\epsilon > 0$

- ϵ is a tolerance parameter: how much error around θ ?

Convergence in Probability

Definition

We will say the sequence $\hat{\theta}_n$ converges in probability to θ (perhaps a non-degenerate RV) if,

$$\lim_{n \rightarrow \infty} \text{Prob}(|\hat{\theta}_n - \theta| > \epsilon) = 0$$

For any $\epsilon > 0$

- ϵ is a tolerance parameter: how much error around θ ?
- In the limit, convergence in probability implies the $\hat{\theta}_n$ distribution collapses on a spike at θ

Convergence in Probability

Definition

We will say the sequence $\hat{\theta}_n$ converges in probability to θ (perhaps a non-degenerate RV) if,

$$\lim_{n \rightarrow \infty} \text{Prob}(|\hat{\theta}_n - \theta| > \epsilon) = 0$$

For any $\epsilon > 0$

- ϵ is a tolerance parameter: how much error around θ ?
- In the limit, convergence in probability implies the $\hat{\theta}_n$ distribution collapses on a spike at θ
- $\{\hat{\theta}_i\}$ does not need actually converge to θ , only $P(|\theta_n - \theta| > \epsilon) = 0$

Definition

$\hat{\theta}_n$, with cdf $F_n(x)$, converges in distribution to random variable Y with cdf $F(x)$ if

$$\lim_{n \rightarrow \infty} |F_n(x) - F(x)| = 0$$

For all $x \in \Re$ where $F(x)$ is continuous.

- Says that cdfs are equal, says nothing about convergence of underlying RV

Convergence in Distribution

Definition

$\hat{\theta}_n$, with cdf $F_n(x)$, converges in distribution to random variable Y with cdf $F(x)$ if

$$\lim_{n \rightarrow \infty} |F_n(x) - F(x)| = 0$$

For all $x \in \Re$ where $F(x)$ is continuous.

- Says that cdfs are equal, says nothing about convergence of underlying RV
- Useful for justifying use of some sampling distributions

Central Limit Theorem

Proposition

Let X_1, X_2, \dots be a sequence of independent random variables with mean μ and variance σ^2 . Let X_i have a cdf $P(X_i \leq x) = F(x)$ and moment generating function $M(t) = E[e^{tX_i}]$. Let $S_n = \sum_{i=1}^n X_i$. Then

$$\lim_{n \rightarrow \infty} P\left(\frac{S_n - \mu n}{\sigma \sqrt{n}} \leq x\right) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp\left(-\frac{x^2}{2}\right)$$

Central Limit Theorem

Proposition

Let X_1, X_2, \dots be a sequence of independent random variables with mean μ and variance σ^2 . Let X_i have a cdf $P(X_i \leq x) = F(x)$ and moment generating function $M(t) = E[e^{tX_i}]$. Let $S_n = \sum_{i=1}^n X_i$. Then

$$\lim_{n \rightarrow \infty} P\left(\frac{S_n - \mu n}{\sigma \sqrt{n}} \leq x\right) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp\left(-\frac{x^2}{2}\right)$$

Proof plan:

- 1) Rely on Fact that convergence of MGFs \rightsquigarrow convergence in CDFs
- 2) Show that MGFs, in limit, converge on normal MGF

Proposition

Let F_n be a sequence of cumulative distribution functions with the corresponding moment generating functions M_n . F be a cdf with the moment generating functions M . If $\lim_{n \rightarrow \infty} M_n(t) \rightarrow M(t)$ for all t in some interval, then $F_n(x) \rightsquigarrow F(x)$ for all x (when F is continuous).

Proposition

Suppose $\lim_{n \rightarrow \infty} a_n \rightarrow a$, then

$$\lim_{n \rightarrow \infty} \left(1 + \frac{a_n}{n}\right)^n = e^a$$

Proposition

Suppose $M(t)$ is a moment generating function some random variable X . Then $M(0) = 1$.

Proof of Central Limit Theorem

Proof. Suppose X_1, \dots, X_n are iid variables with $E[X] = 0$, variance σ_x^2 , Moment Generating Function (MGF) $M_x(t)$.

Proof of Central Limit Theorem

Proof. Suppose X_1, \dots, X_n are iid variables with $E[X] = 0$, variance σ_x^2 , Moment Generating Function (MGF) $M_x(t)$.

Let $S_n = \sum_{i=1}^n X_i$ and $Z_n = \frac{S_n}{\sigma_x \sqrt{n}}$.

Proof of Central Limit Theorem

Proof. Suppose X_1, \dots, X_n are iid variables with $E[X] = 0$, variance σ_x^2 , Moment Generating Function (MGF) $M_x(t)$.

Let $S_n = \sum_{i=1}^n X_i$ and $Z_n = \frac{S_n}{\sigma_x \sqrt{n}}$.

$$M_{S_n} = (M_x(t))^n \text{ and } M_{Z_n}(t) = \left(M_x \left(\frac{t}{\sigma_x \sqrt{n}} \right) \right)^n$$

Proof of Central Limit Theorem

Proof. Suppose X_1, \dots, X_n are iid variables with $E[X] = 0$, variance σ_x^2 , Moment Generating Function (MGF) $M_x(t)$.

Let $S_n = \sum_{i=1}^n X_i$ and $Z_n = \frac{S_n}{\sigma_x \sqrt{n}}$.

$$M_{S_n} = (M_x(t))^n \text{ and } M_{Z_n}(t) = \left(M_x \left(\frac{t}{\sigma_x \sqrt{n}} \right) \right)^n$$

Using Taylor's Theorem we can write

$$M_x(s) = M_x(0) + sM'_x(0) + \frac{1}{2}s^2M''_x(0) + e_s$$

$$e_s/s^2 \rightarrow 0 \text{ as } s \rightarrow 0.$$

$$M_x(s) = M_x(0) + sM'_x(0) + \frac{1}{2}s^2M''_x(0) + e_s$$

Filling in the values we have

$$M_x(s) = 1 + 0 + \frac{\sigma_x^2}{2}s^2 + \underbrace{e_s}_{\text{Goes to zero}}$$

Set $s = \frac{t}{\sigma_x\sqrt{n}}$ $\lim_{n \rightarrow \infty} s \rightarrow 0$. Then

$$\begin{aligned} M_{Z_n}(t) &= \left(1 + \frac{\sigma_x^2}{2} \left(\frac{t}{\sigma_x\sqrt{n}} \right)^2 \right)^n \\ &= \left(1 + \frac{t^2/2}{n} \right)^n \\ \lim_{n \rightarrow \infty} M_{Z_n}(t) &= e^{\frac{t^2}{2}} \end{aligned}$$
